

Flip versus stabilization

TAIL_ONLY: every measured chain flip
lies past n_{stab}

Stefan Hamann

August 30, 2026

Abstract

Extraction consumes only $\text{fullRead}(W, f)$ for $\text{meshExp}(f) \leq m$ after onset $a \geq a_0(f)$ — the stabilized band, where $\text{fullRead} = \text{weilForm}$. The r448 flips sit at $n/N \in [0.54, 0.99]$. This note operationalizes n_{stab} by a window comparison of Chebyshev moments (skip m_0, m_1 ; first disagreement with neighbours $k_z \pm 1, \pm 2$). The cut is identical from $\varepsilon = 10^{-6}$ to 10^{-2} . Every measured flip lies strictly past n_{stab} . Prefix $q^\dagger$ on the stabilized depth is living ($\delta \in [0.093, 0.129]$). The construction lives for extraction. No RH claim. No anti-RH claim.

Status. No new SATZ. Propositions 1–3 are a named infra census. Ausgang TAIL_ONLY / PREFIX_LIVE / SLICE_FLOOR_STANDS / MINCUT_IS_PREFIX. No L^* claim. No $R^\dagger$ claim. No RH claim. No anti-RH claim.

1 Method

Proposition 1 (n_{stab} by Fenster-Vergleich). *Let $m_n(W)$ be the n -th Chebyshev moment of the folded $\tilde{\mu}$ of window W . Skip m_0, m_1 (window scale / dipole). Then*

$$n_{\text{stab}}(W_k) = \min\{n \geq 2 : \text{rel}(m_n(W_k), m_n(W_{k'})) > \varepsilon \text{ for a neighbour } k'\}.$$

On the living pair $k_z 17/18$ the first break is $n = 18$, identical for $\varepsilon \in \{10^{-5}, \dots, 10^{-2}\}$ — flat grades agree (comb-stab anchor); the cut is mesh-limited, not an ε -artefact. Deep windows share the same ε -robustness (the cut does not move from 10^{-6} to 10^{-2}).

This is the operational form of “the n -th read already equals the limit”: once neighbouring windows agree, the grade is window-independent and is a Weil value (comb channel: proved `comb.elementwise.stabilization`).

2 The table

k_z	N	n_{stab}	n_{flip}	n_{stab}/N	class
136	1641	175	—	0.107	live
137	8300	175	8283	0.021	TAIL
170	5771	194	5515	0.034	TAIL
197	4071	406	3788	0.100	TAIL
230	2012	194	1818	0.096	TAIL
500	17847	1525	9564 ^f	0.085	TAIL

^ffloat first-flip (r448). Exact first-flips: r447/r448, dps-stable at $k = 10$ and $k_z 230$.

Proposition 2 (TAIL_ONLY). *On every measured deep window, $n_{\text{flip}} > n_{\text{stab}}$. The chain break sits in the non-stabilized tail. Extraction does not consume that tail. There is no prefix-hit and therefore no anti-RH candidate.*

3 Prefix $R^\dagger$

Proposition 3 (Prefix lives). *The depth-80 compression (inside every n_{stab} above) has $n_{\text{flip}} = 0$ and*

$$\delta_{80}(k_z136, \dots, 500) \in \{0.129, 0.100, 0.106, 0.112, 0.127, 0.093\}.$$

All $q_{80}^\dagger < 1$. The r445 slice $k = 5..9$ floor $\delta_\infty = +0.02741$ stands; the prefix values sit above it.

Dead CHI3-15: $n_{\text{flip}} = 0$, $q^\dagger = 1.023$ (edge / pole overshoot). No chain flip, so no prefix-hit; consistent with the prefix picture.

Mincut repair (sketch, not built). The load-bearing Lean mincut (`frequently_selected_augDualResolve` r430/r434) already consumes `fullRead` only for $\text{meshExp}(f) \leq m$ after onset — exactly the stabilized prefix, not the ABD tail. Python “ABD-dead” is a tail statement. What changes: name the compression $R^\dagger(W|_{n \leq n_{\text{stab}}})$ as the object the frequently-quantifier talks about; no new `sorry` if that object is identified with the existing plain-read cone. The cofinal question is again open-living on every window, including the tail-dead deep ones.

Claim boundary

Nothing here is evidence for or against the Riemann hypothesis, in either direction. A prefix-hit would have opened a scepticism cascade, not an anti-RH claim; none occurred. The identities are a finite moment/chain census.
